

# Thoughts on Systems for Large Datasets: Problems and Opportunities

Jeff Dean  
Google Senior Fellow  
[jeff@google.com](mailto:jeff@google.com)

Many of the systems mentioned in this talk represent joint work with many, many colleagues at Google

# Areas I Wish New Grads Knew More About

- Ability to do **back-of-the-envelope calculations** and quickly evaluate many alternative designs
- Understanding the importance of **locality** at all levels (caches & memory systems, disk I/O, cross-machine, geographic regions, etc.)
- Low-level **encoding and compression** schemes and their tradeoffs
- More math and statistics knowledge
  - e.g. use of **randomized, probabilistic algorithms** in distributed systems

# Overview

- A collection of problems I believe are difficult/interesting:
  - For some, significant work has been done/published
  - Others are less explored
- Not meant to be exhaustive catalog of problems/areas
  - I care (and Google cares) about many other problems, too!
- Roughly in two main areas:
  - issues that arise in building systems that store and manipulate large datasets
  - automatically extracting higher-level information from raw data
- Feedback and suggestions are welcome!

# Programming Models

- Large datasets already require use of large numbers of cores and machines for analyses
- Moore's law is now scaling # cores instead of MHz
  - parallelism likely to be even more important in the future
- Parallelism is key to getting good performance out of large-scale systems

# Distributed Systems Abstractions

- High-level tools/languages/abstractions for building distributed systems
  - e.g. For batch processing, MapReduce handles parallelization, load balancing, fault tolerance, I/O scheduling automatically within a simple programming model
- Challenge: Are there unifying abstractions for other kinds of distributed systems problems?
  - e.g. systems for handling interactive requests & dealing with *intra*-operation parallelism
    - load balancing, fault-tolerance, service location & request distribution, ...
  - systems that seamlessly divide, expand, and contract processing subsystems?

# Building Applications on top of Weakly Consistent Storage Systems

- Many applications need state replicated across a wide area
  - For reliability and availability
- Two main choices:
  - consistent operations (e.g. use Paxos)
    - often imposes additional latency for common case
  - inconsistent operations
    - better performance/availability, but apps harder to write and reason about in this model
- Many apps need to use a mix of both of these:
  - e.g. Gmail: marking a message as read is asynchronous, sending a message is a heavier-weight consistent operation

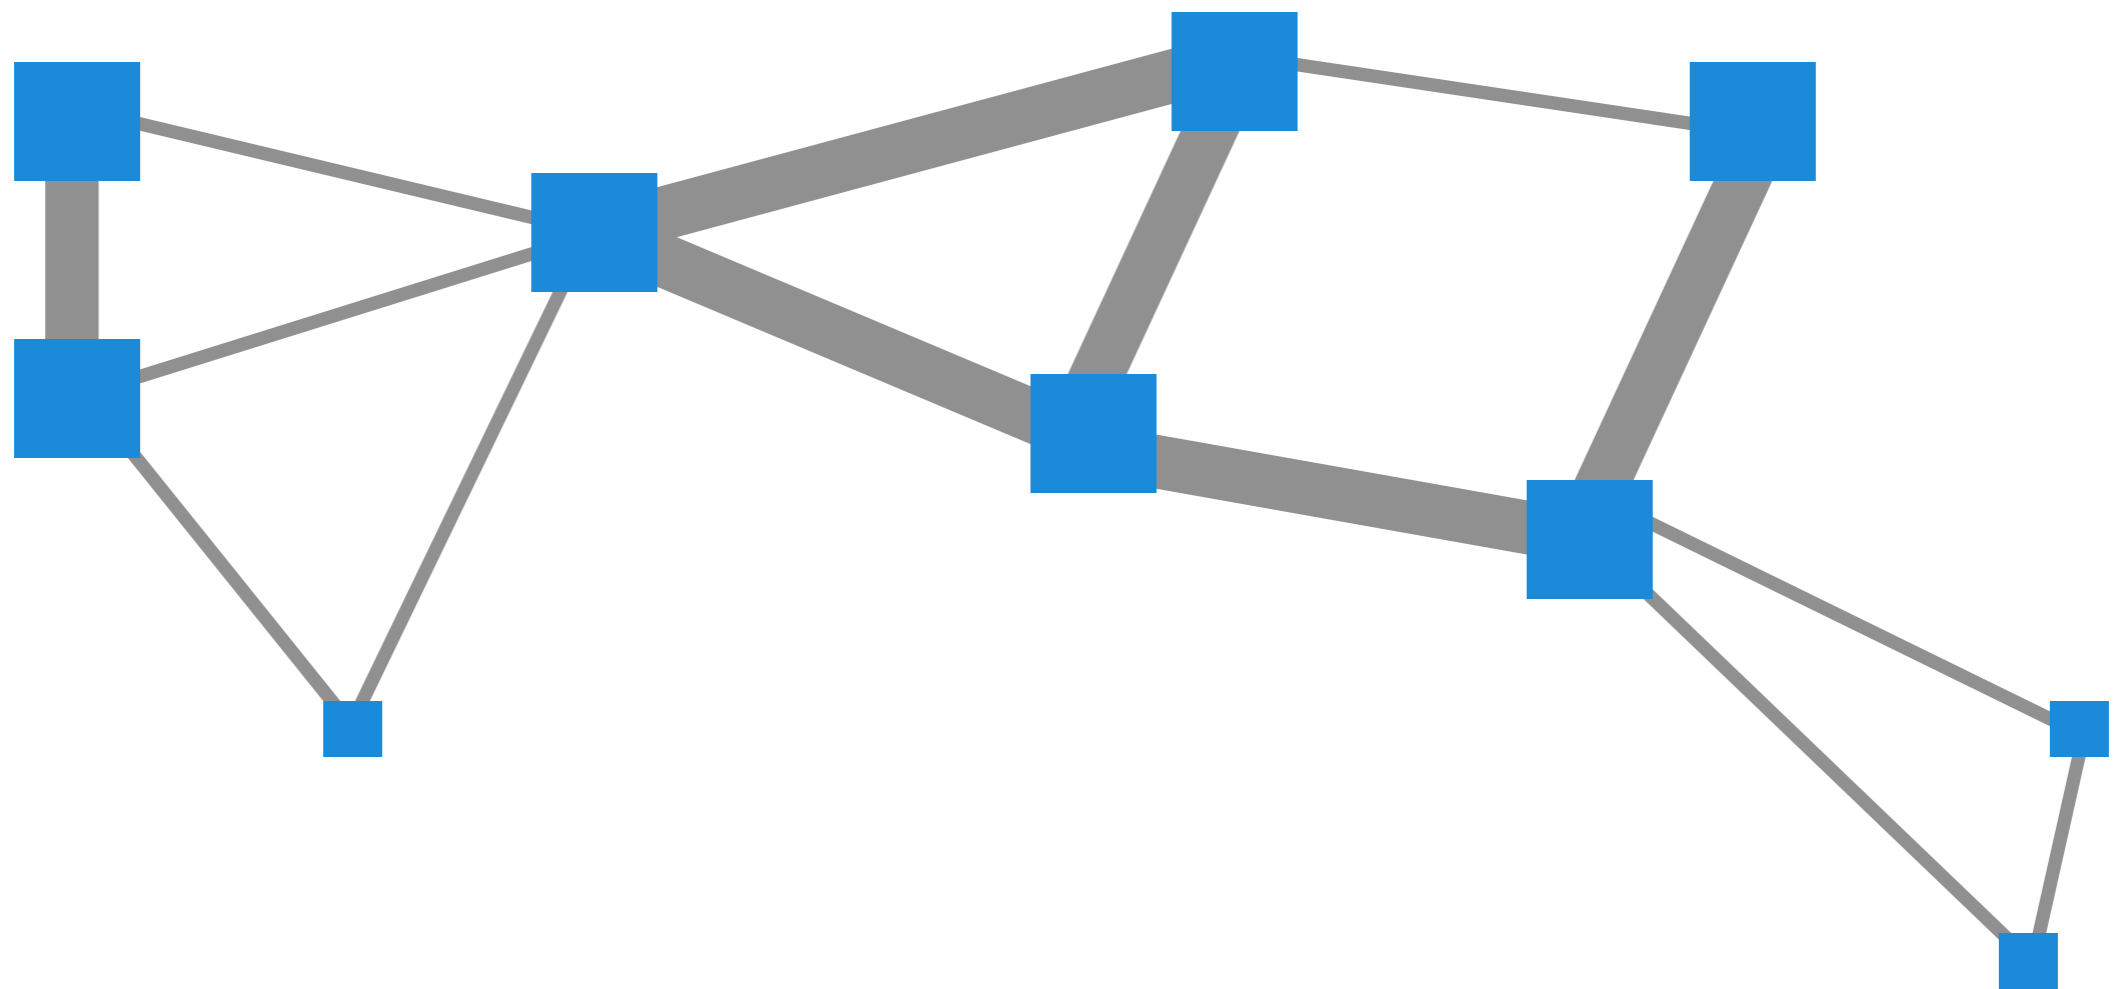

# Building Applications on top of Weakly Consistent Storage Systems

- Challenge: General model of consistency choices, explained and codified
  - ideally would have one or more “knobs” controlling performance vs. consistency
  - “knob” would provide easy-to-understand tradeoffs
- Challenge: Easy-to-use abstractions for resolving conflicting updates to multiple versions of a piece of state
  - Useful for reconciling client state with servers after disconnected operation
  - Also useful for reconciling replicated state in different data centers after repairing a network partition

# Design of Very Large-Scale Computer Systems

- Future scale:  $\sim 10^6$  to  $10^7$  machines, spread at 100s to 1000s of locations around the world,  $\sim 10^9$  client machines

- zones of semi-autonomous control
- consistency after disconnected operation
- power adaptivity

# Adaptivity and Self-Tuning in World-Wide Systems

- Challenge: automatic, dynamic world-wide placement of data & computation to minimize latency and/or cost, given constraints on:
  - bandwidth
  - packet loss
  - power
  - resource usage
  - failure modes
  - ...
- Users specify high-level desires:
  - “99%ile latency for accessing this data should be <50ms”*
  - “Store this data on at least 2 disks in EU, 2 in U.S. & 1 in Asia”*

# ACLs in Information Retrieval Systems

- Retrieval systems with mix of private, semi-private, widely shared and public documents
  - e.g. e-mail vs. shared doc among 10 people vs. messages in group with 100,000 members vs. public web pages
- Challenge: building retrieval systems that efficiently deal with ACLs that vary widely in size
  - best solution for doc shared with 10 people is different than for doc shared with the world
  - sharing patterns of a document might change over time

# Automatic Construction of Efficient IR Systems

- Currently use several retrieval systems
  - e.g. one system for sub-second update latencies, one for very large # of documents but daily updates, ...
  - common interfaces, but very different implementations primarily for efficiency
  - works well, but lots of effort to build, maintain and extend different systems
- Challenge: can we have a single parameterizable system that automatically constructs efficient retrieval system based on these parameters?

# Information Extraction from Semi-structured Data

- Data with clearly labelled semantic meaning is a tiny fraction of all the data in the world
- But there's lots semi-structured data
  - books & web pages with tables, data behind forms, ...
- Challenge: algorithms/techniques for improved extraction of structured information from unstructured/semi-structured sources
  - noisy data, but lots of redundancy
  - want to be able to correlate/combine/aggregate info from different sources

# Learning from Raw Data

- Large datasets of very raw data
  - images, videos, user activity logs, genetics, other sciences, ...
- Want to answer high-level questions:
  - “what is a user in this situation likely to do?”
  - “which users are likely to buy items for more than \$1000”
  - “give me a textual summary of this video”
  - “what are the most likely genetic markers of this disease, given genetic data and medical records of millions of people?”
  - “find a picture of three scarlet macaws in a tree”
- Need systems that automatically build high level representations and abstractions from the raw data
- Want to generalize from one task to others

# Broadly Applicable

- We have been building systems that apply these techniques in the following domains:
- image recognition, object detection, video processing
- speech recognition
- language modeling
- user activity prediction
- neuroscience
- ad system optimization
- language understanding
- ...

# Plenty of Data

- **Text:** trillions of words of English + other languages
- **Visual:** billions of images and videos
- **Audio:** spoken queries, audio portion of video data, ...
- **User activity:** queries, result page clicks, map requests, etc.
- **Knowledge graph:** billions of labelled relation triples
- **Biology and Health:** genetic data, health care records, ...
- **Physical sciences:** physics, astronomy, ...
- ...

# What is being said?

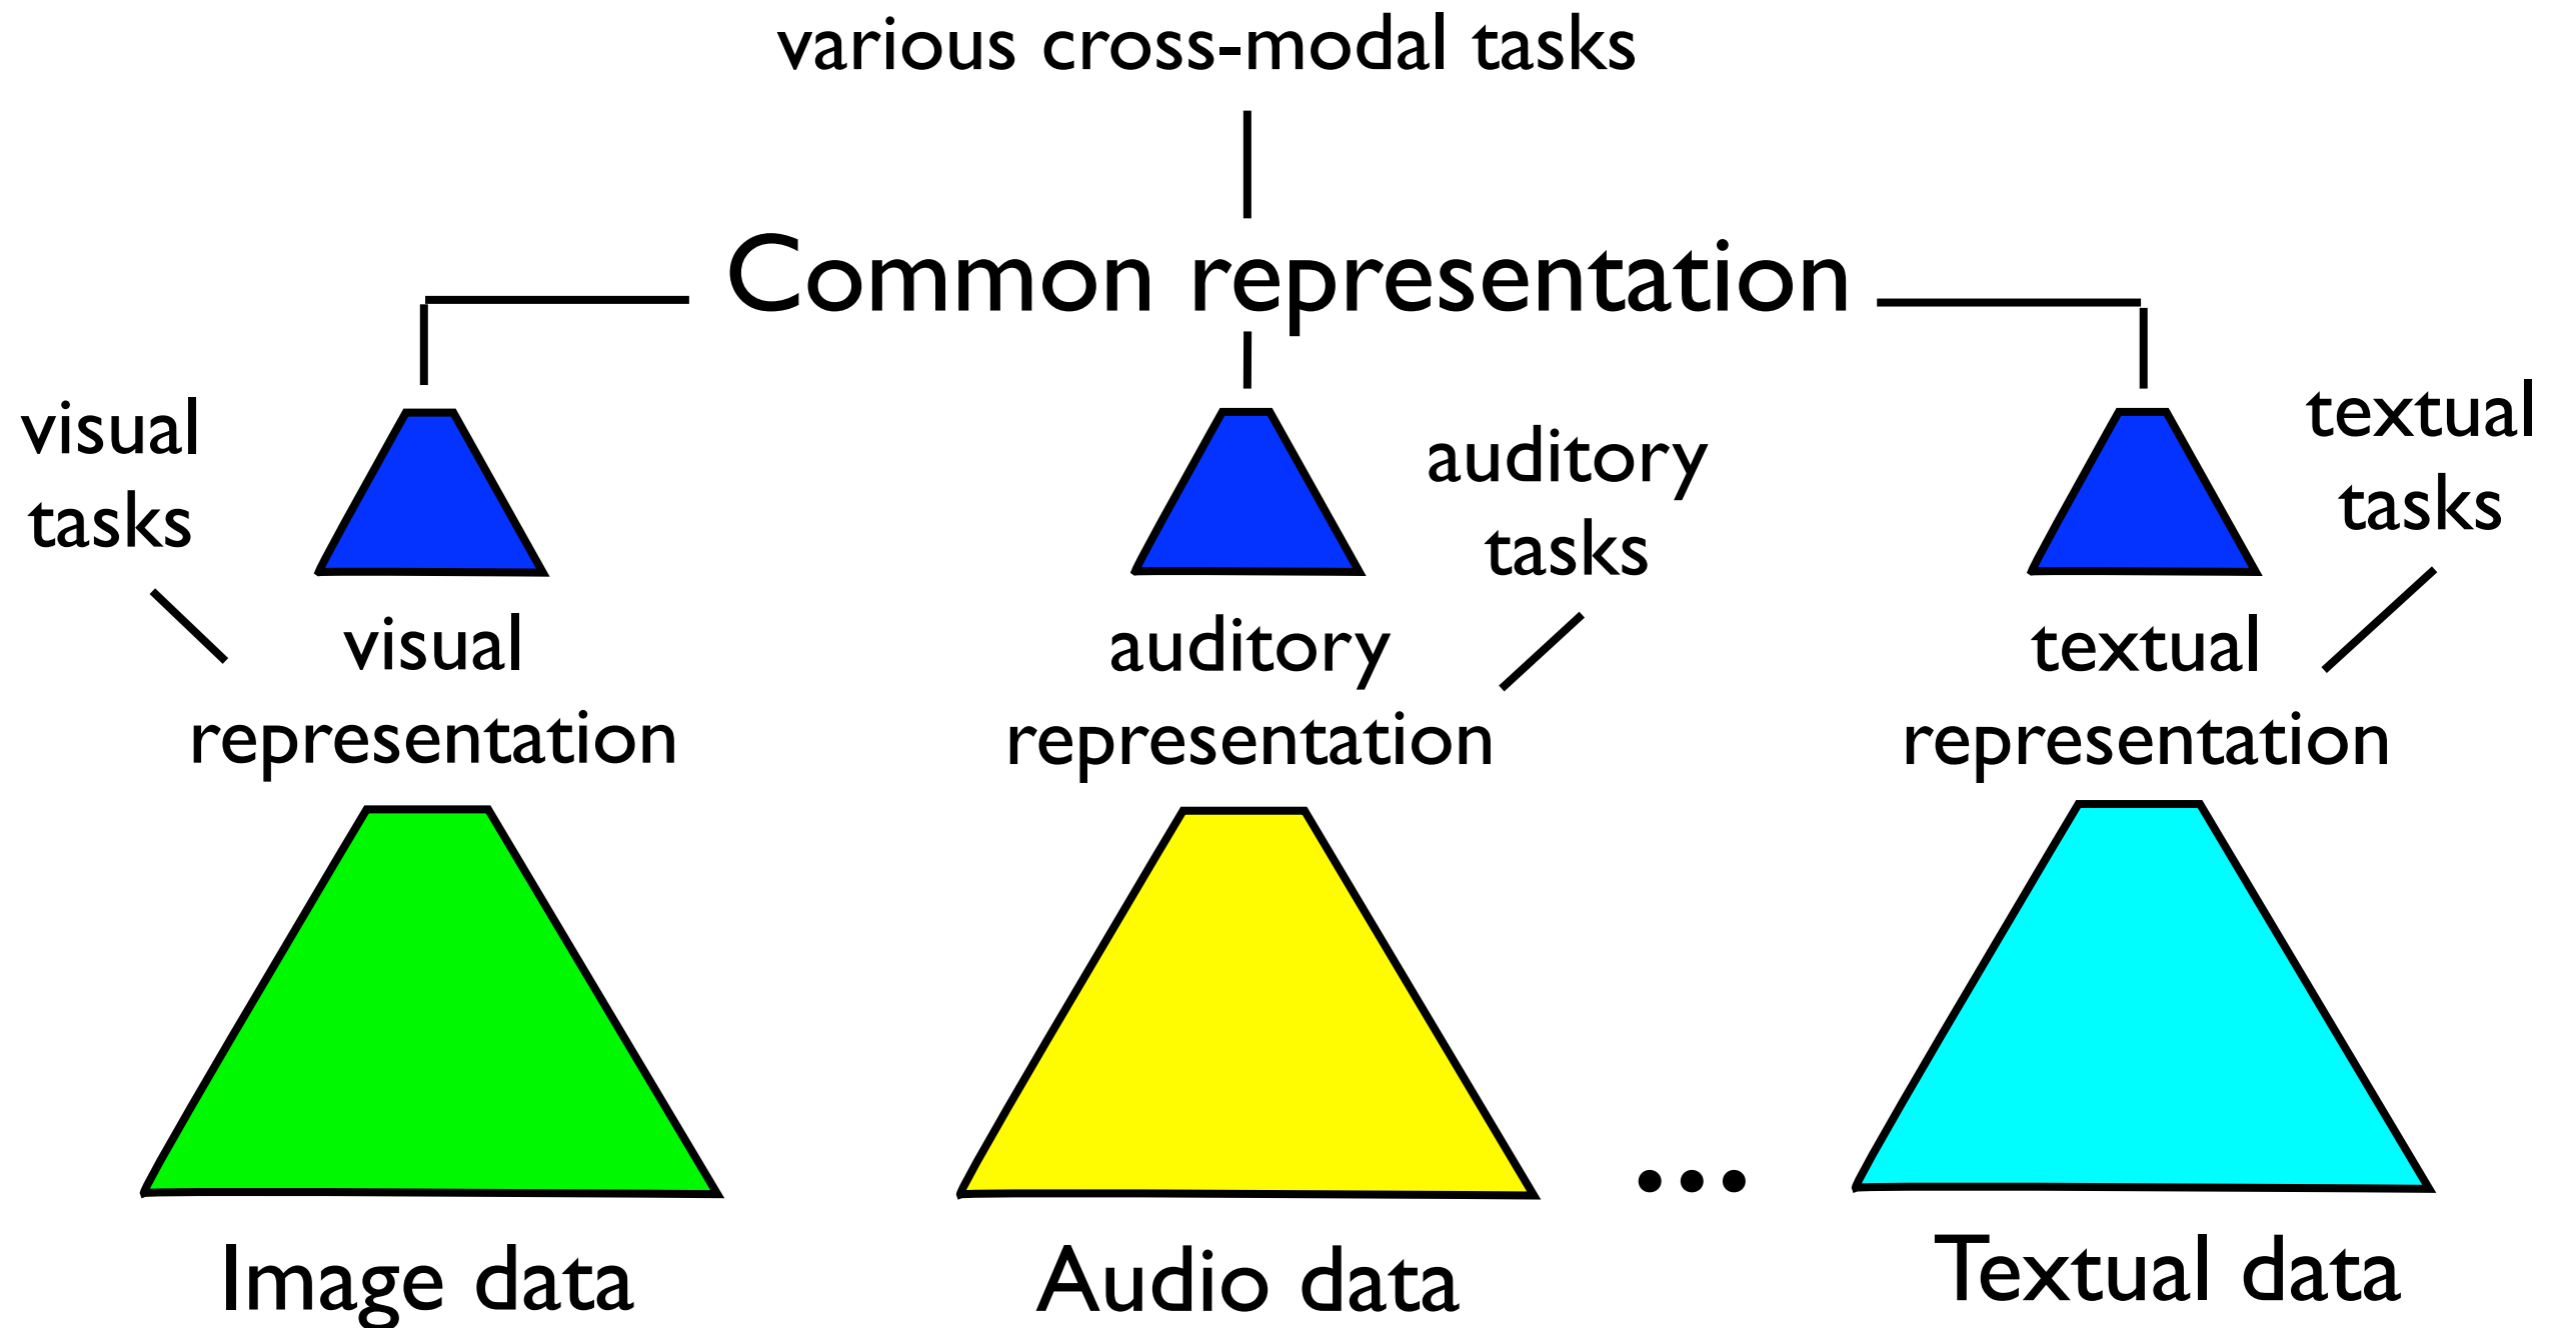

# Goal: Unified System

# Goal: Unified System

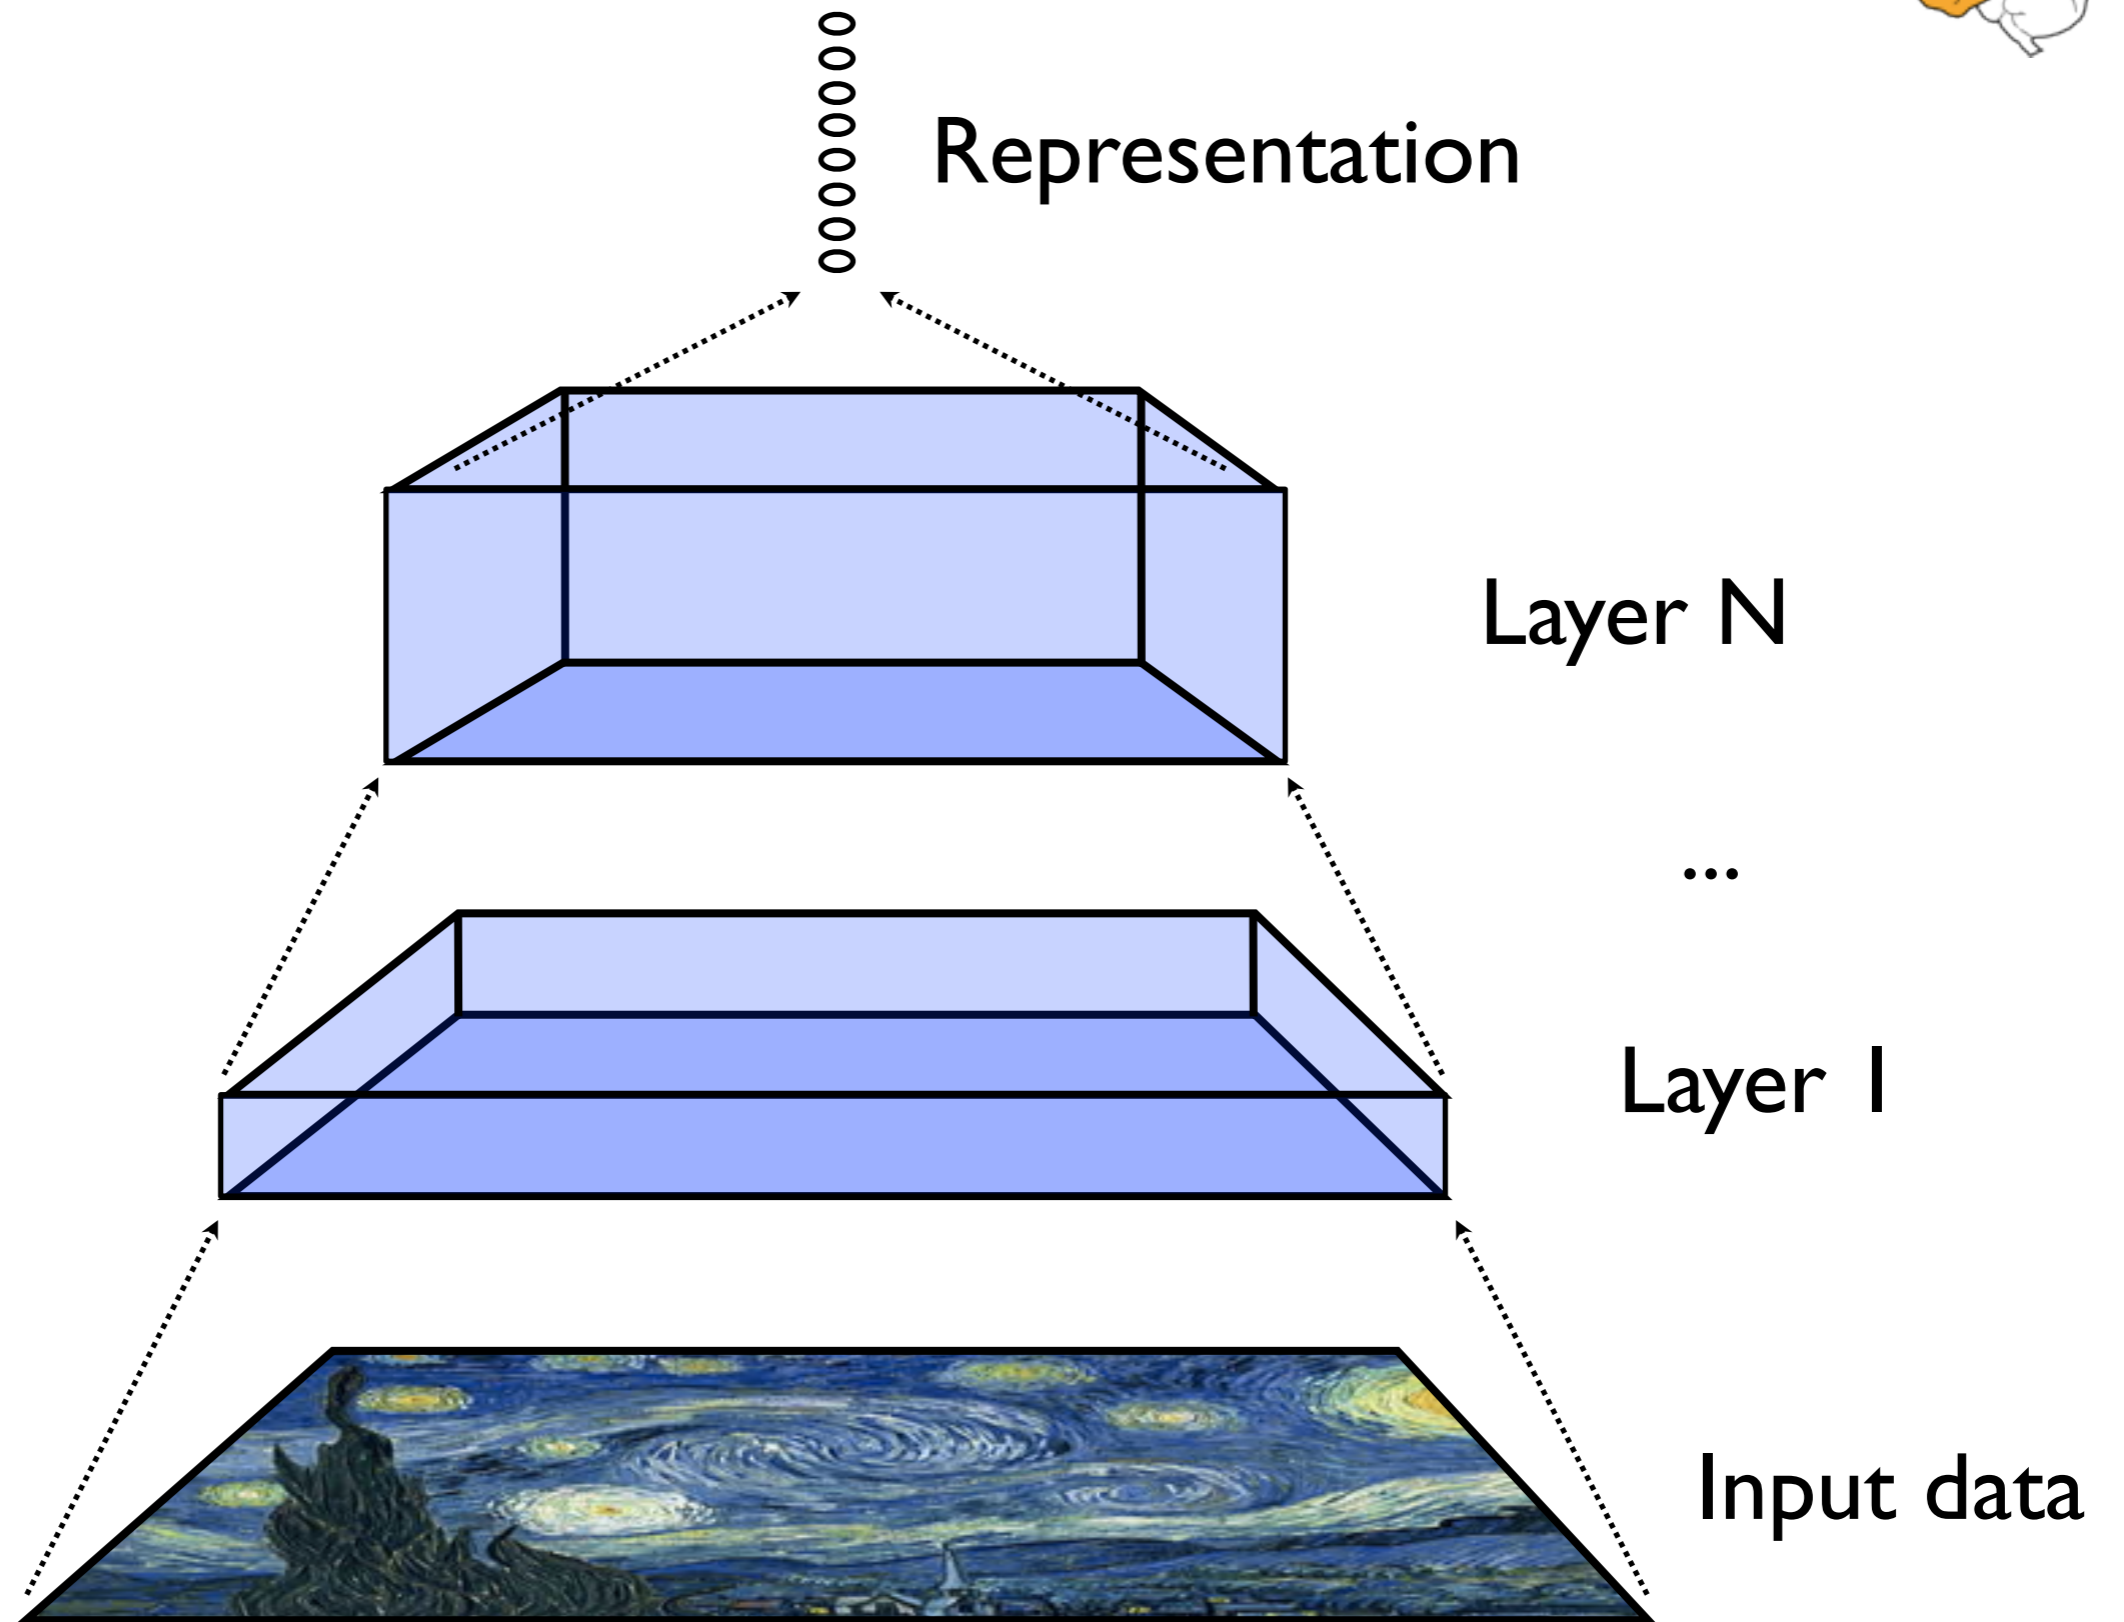

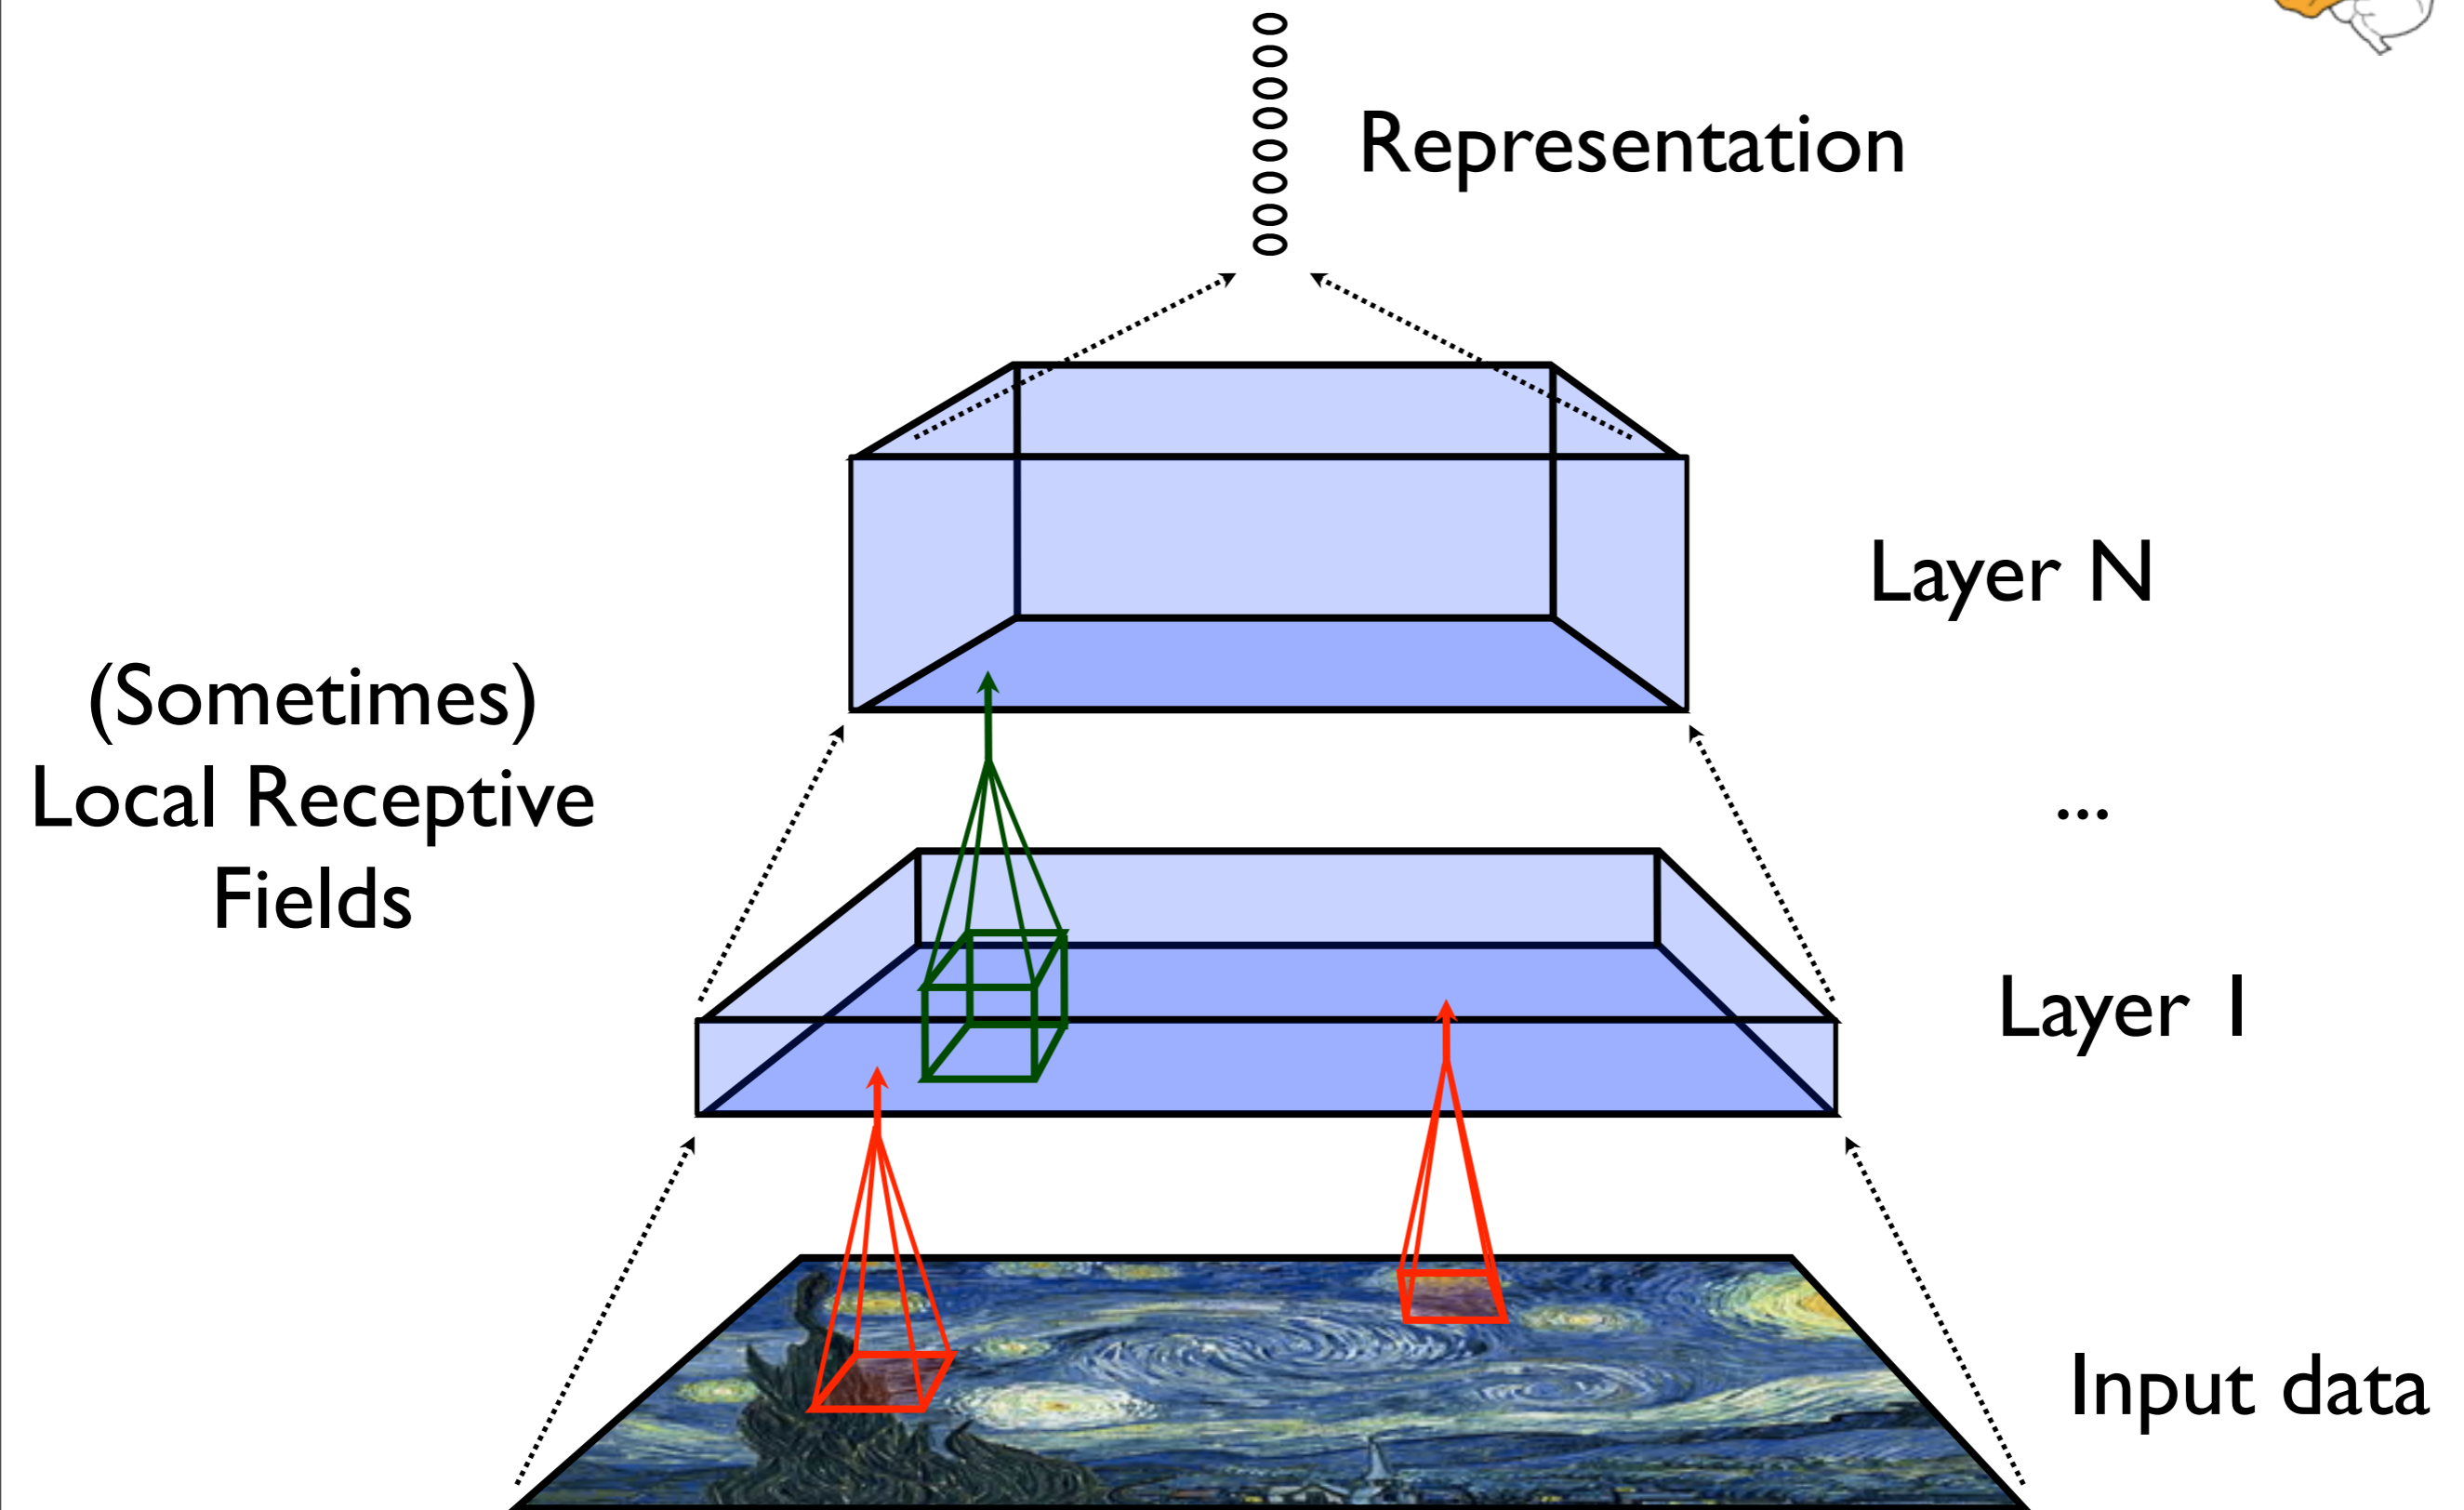

# Goal: Unified System

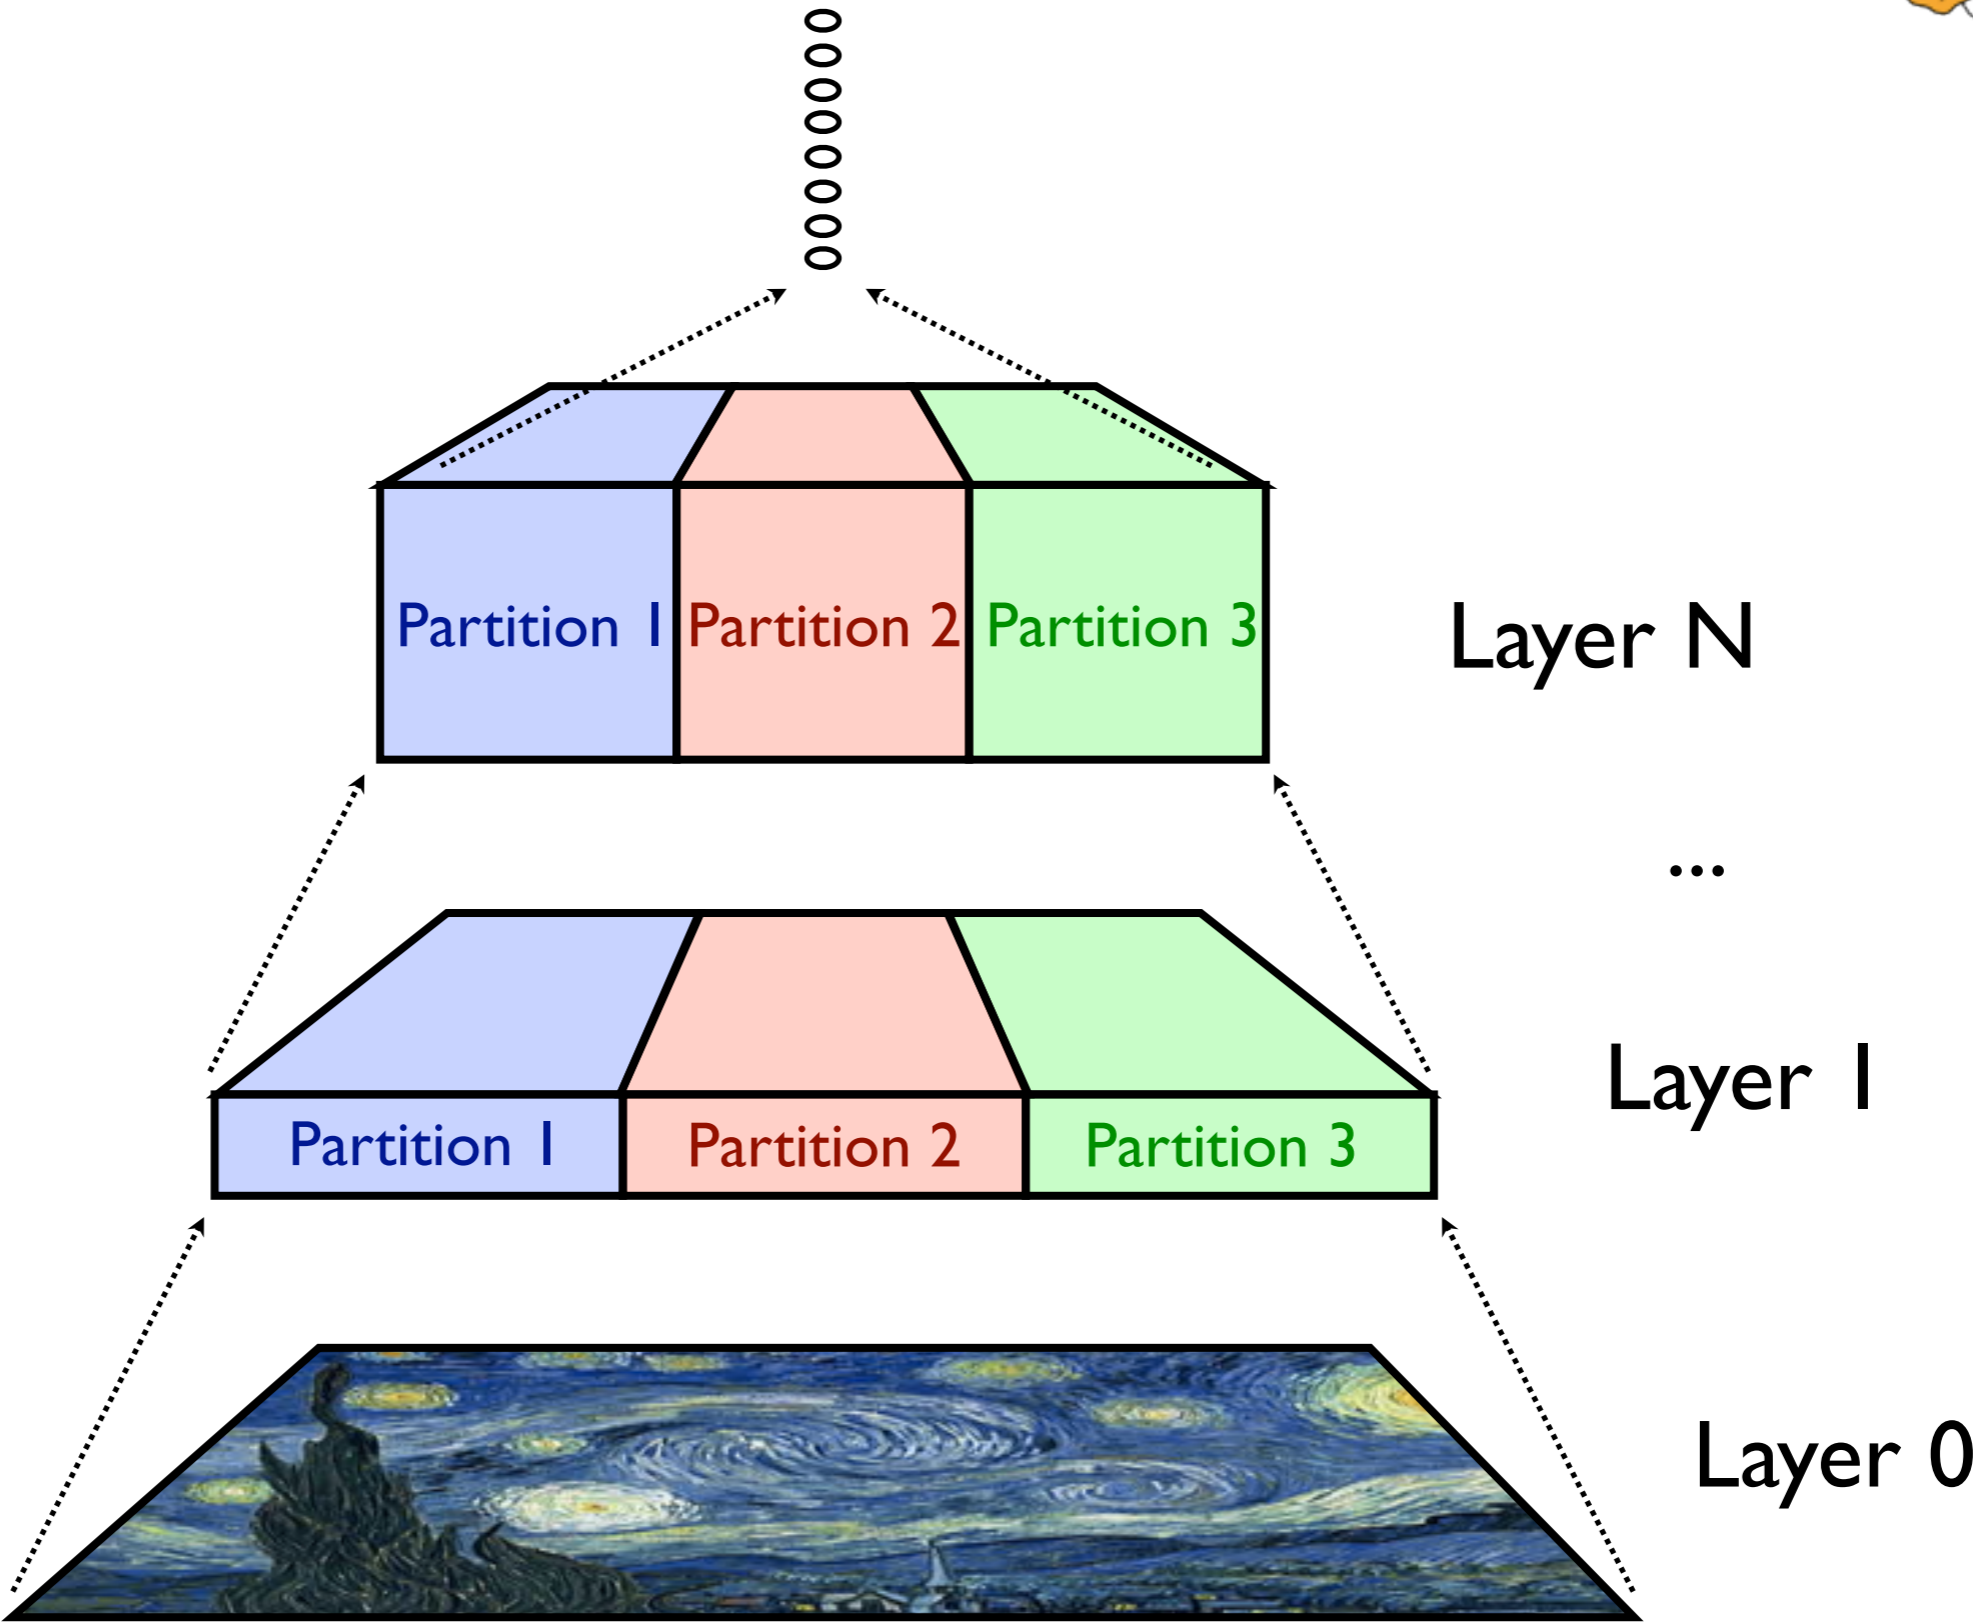

# One Key Approach: Deep Learning

- Algorithmic approach
  - automatically learn high-level representations from raw data
  - can learn from both labeled and unlabeled data
- Recent academic deep learning results improve on state-of-the-art in many areas (Hinton, Ng, Bengio, LeCun, et al.):
  - images, video, speech, NLP, ...
  - ... using modest model sizes ( $\leq \sim 50\text{M}$  parameters)
- We want to scale this to much bigger models & datasets
  - general approach: parallelize at many levels

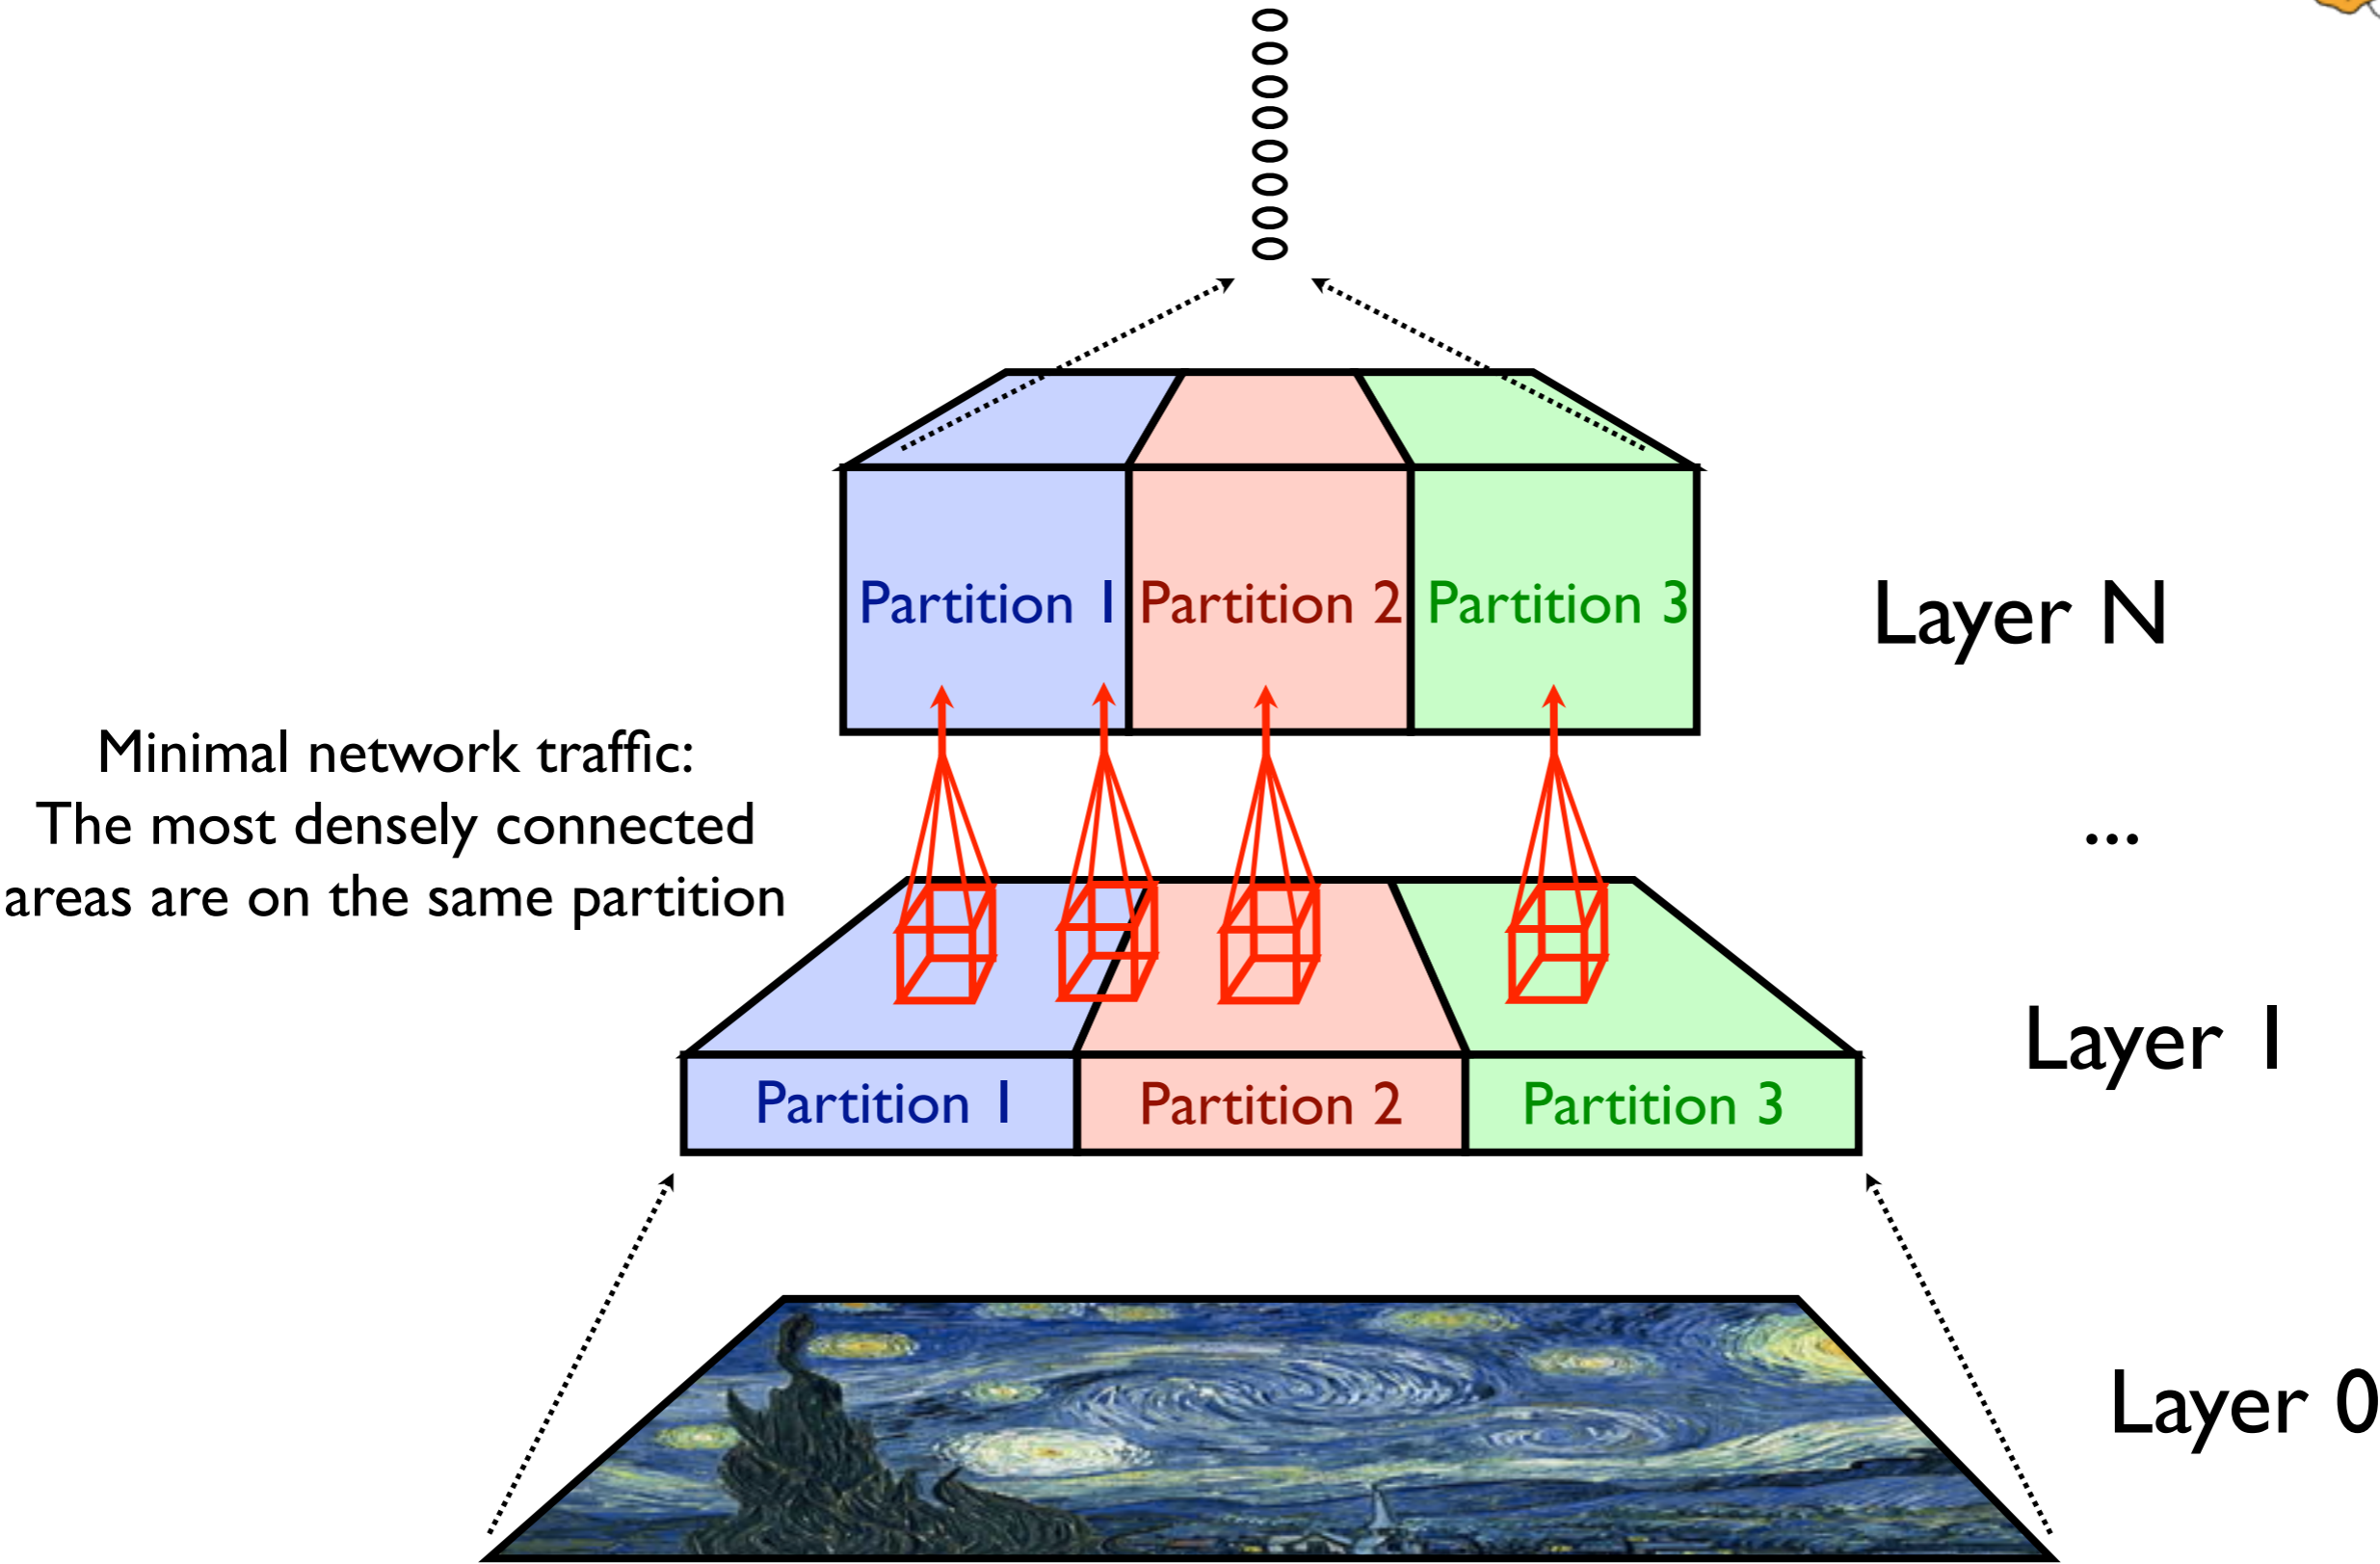

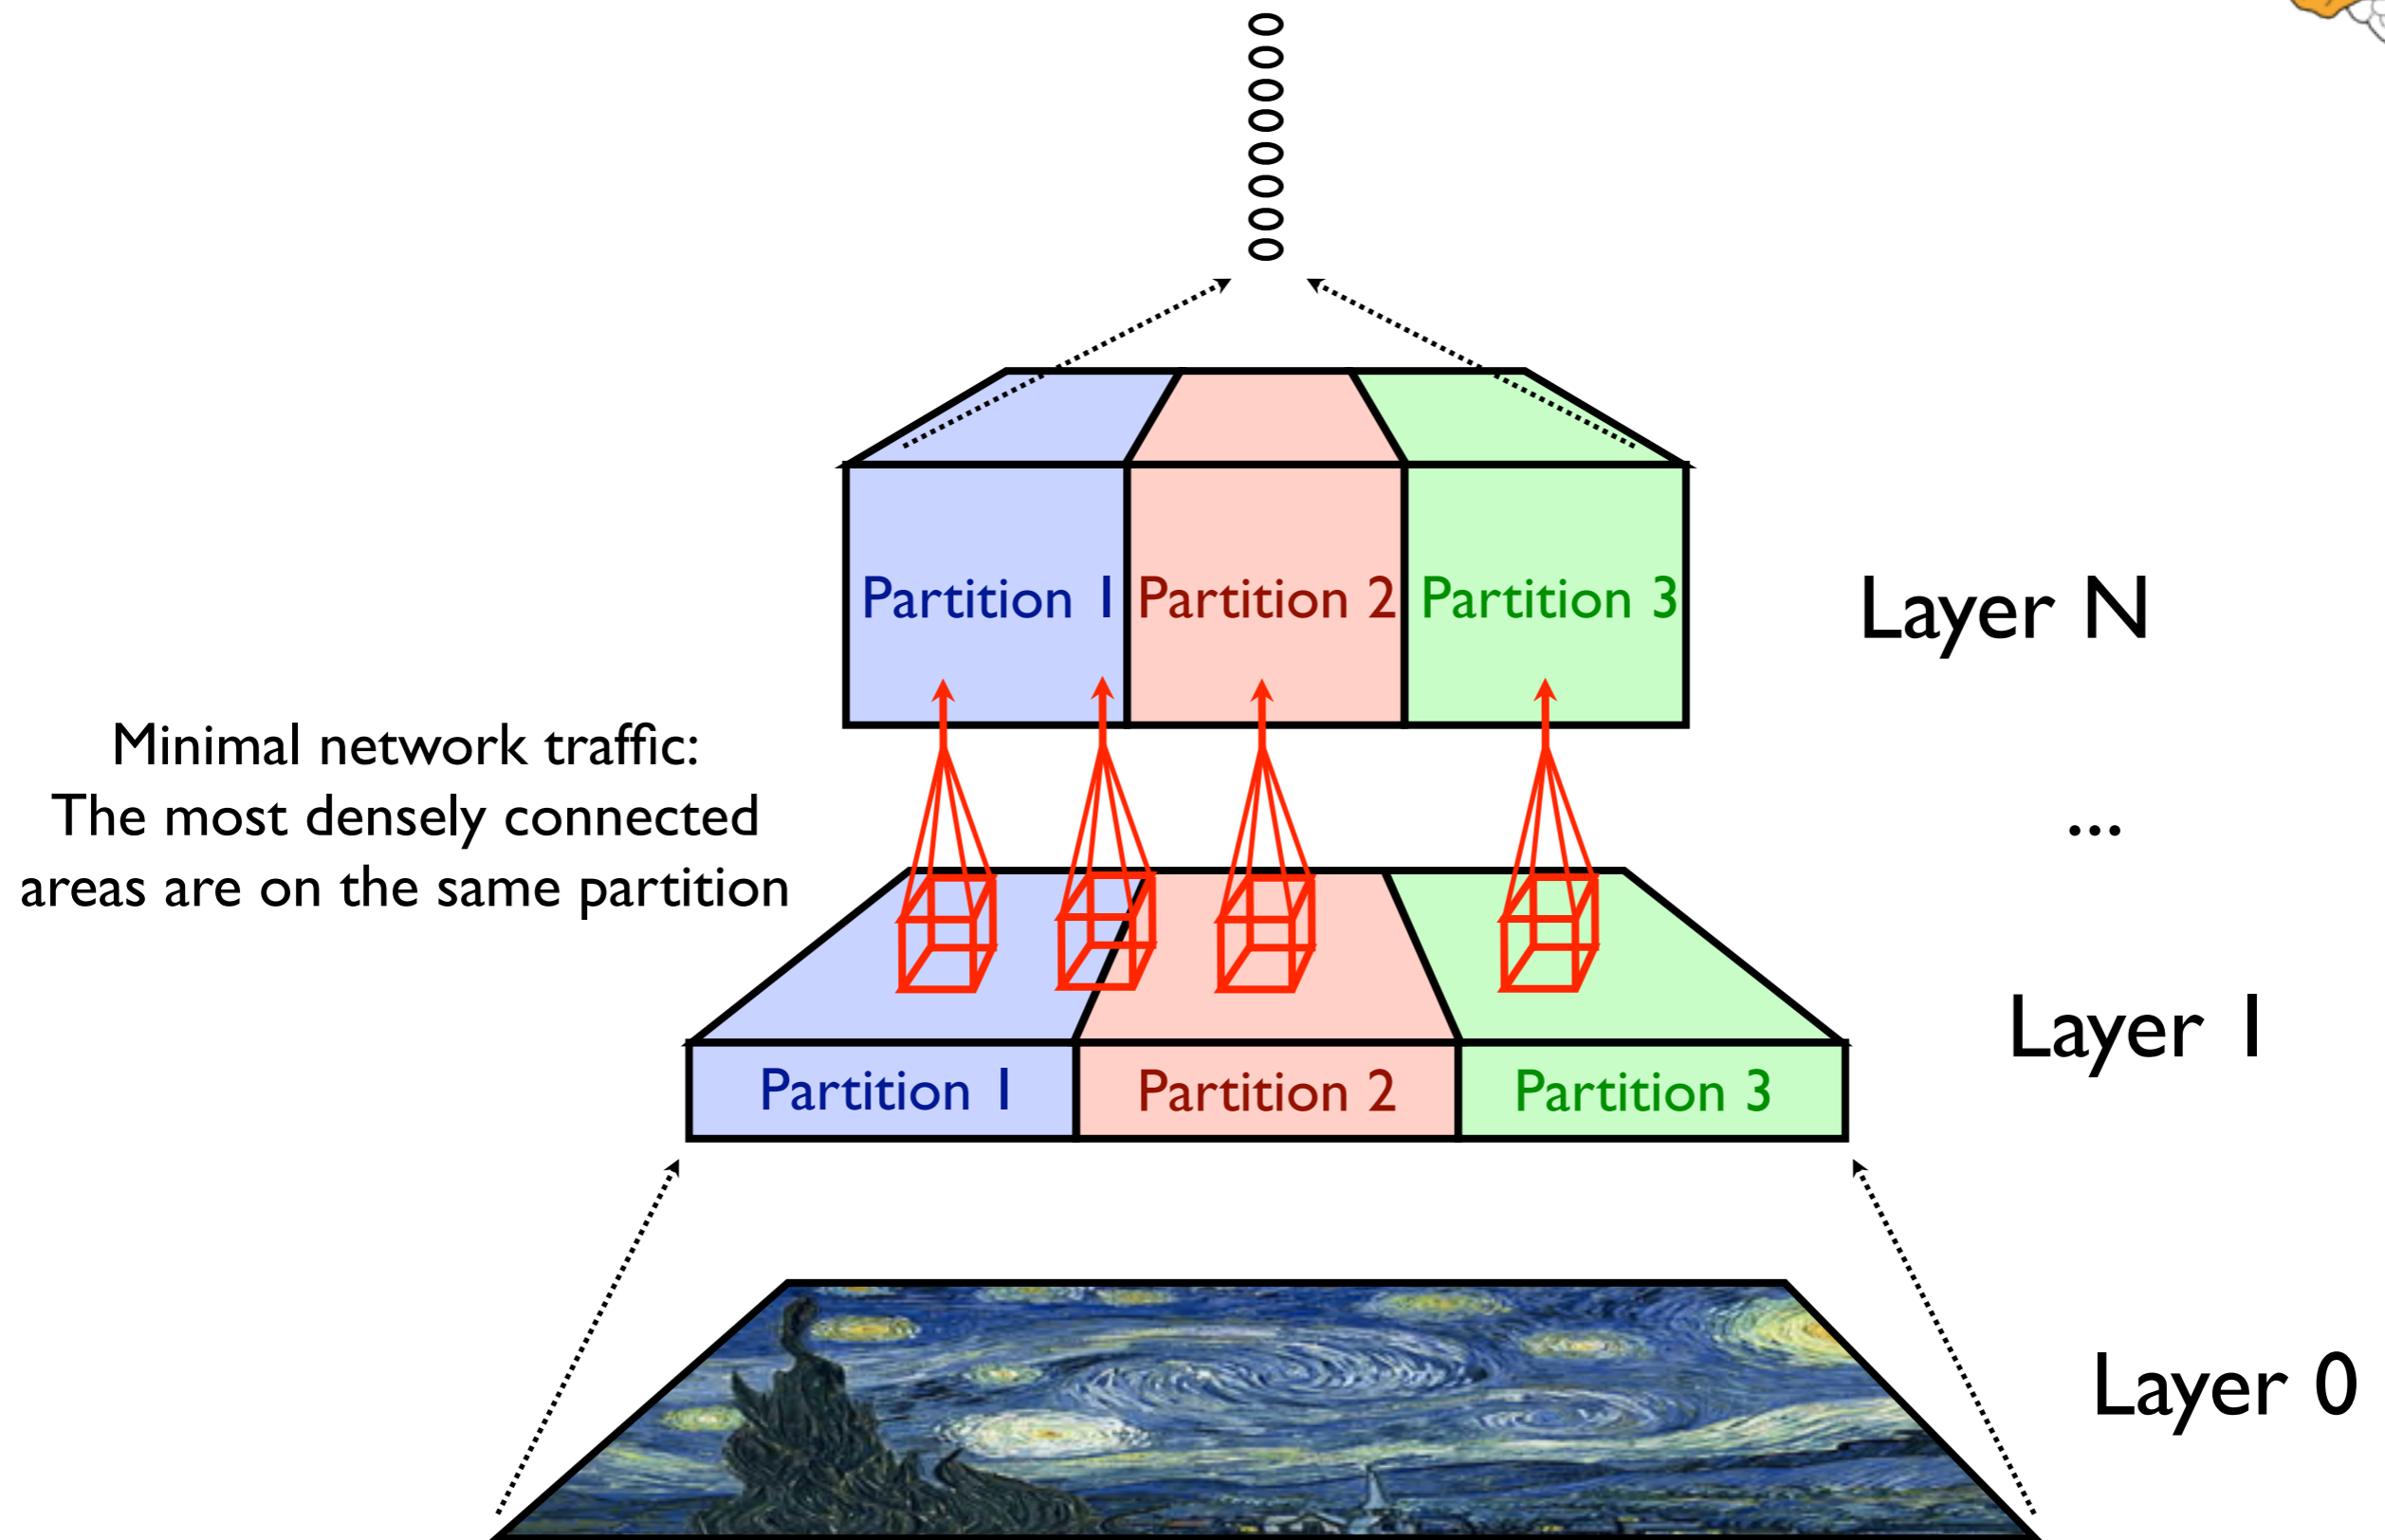

# Partition model across machines

# Partition model across machines

# Partition model across machines

One replica of our biggest model: 144 machines, ~2300 cores

# Initial Focus on Upsupervised Learning

- Always: unlabeled data >> labeled data
- Experiment: unsupervised training on 10M random YouTube frames
- Trained 9 layer model with local connections

Visualization of optimal stimuli for two different neurons in top layer:

# Acoustic Modeling for Speech Recognition

Close collaboration with Google Speech team

Trained in <5 days on cluster of 800 machines

# Acoustic Modeling for Speech Recognition

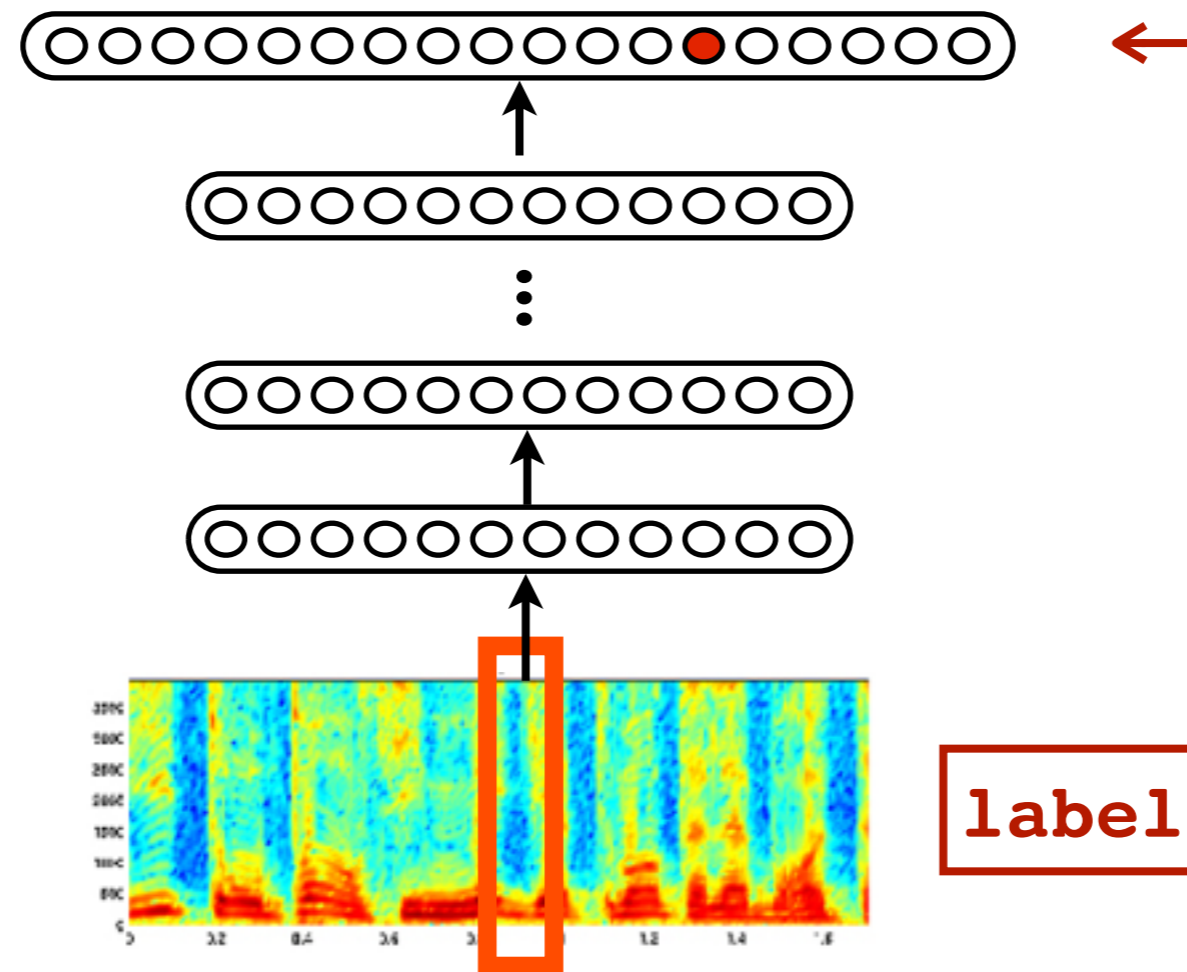

Close collaboration with Google Speech team

Trained in <5 days on cluster of 800 machines

30% reduction in Word Error Rate for English

(“biggest single improvement in 20 years of speech research”)

# Acoustic Modeling for Speech Recognition

Close collaboration with Google Speech team

Trained in <5 days on cluster of 800 machines

30% reduction in Word Error Rate for English  
("biggest single improvement in 20 years of speech research")

Launched at time of Jellybean release of Android

# Convolutional Models for Object Recognition

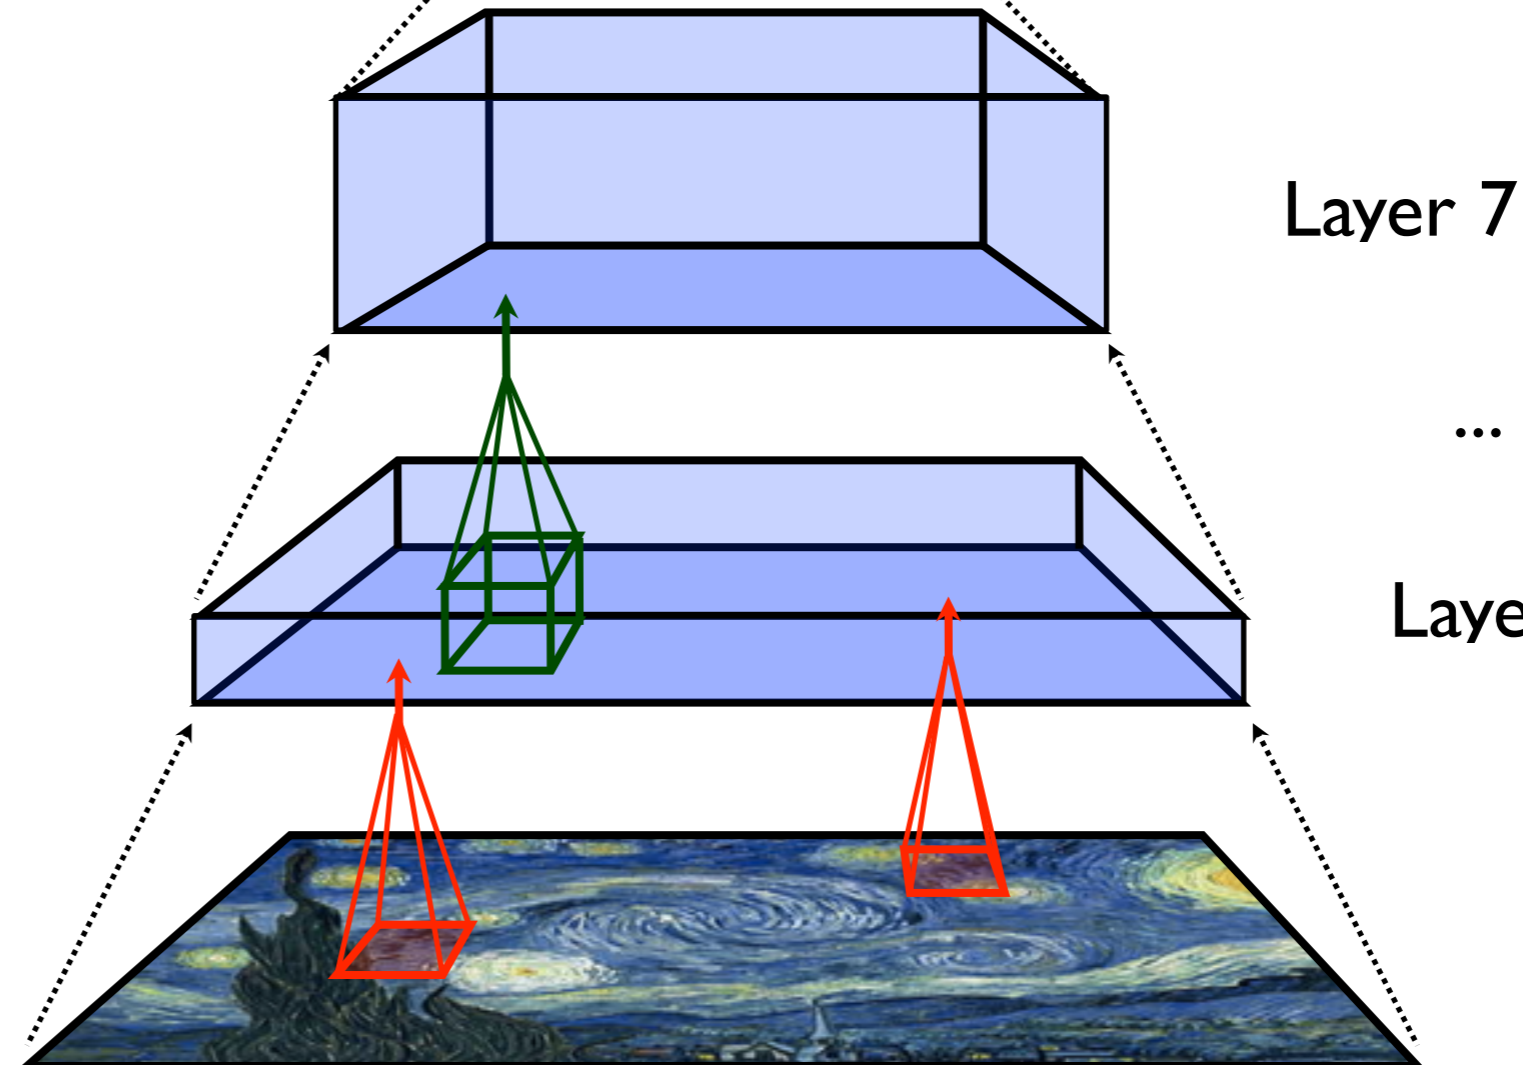

Softmax to predict object class

Fully-connected layers

Convolutional layers  
(same weights used at all  
spatial locations in layer)

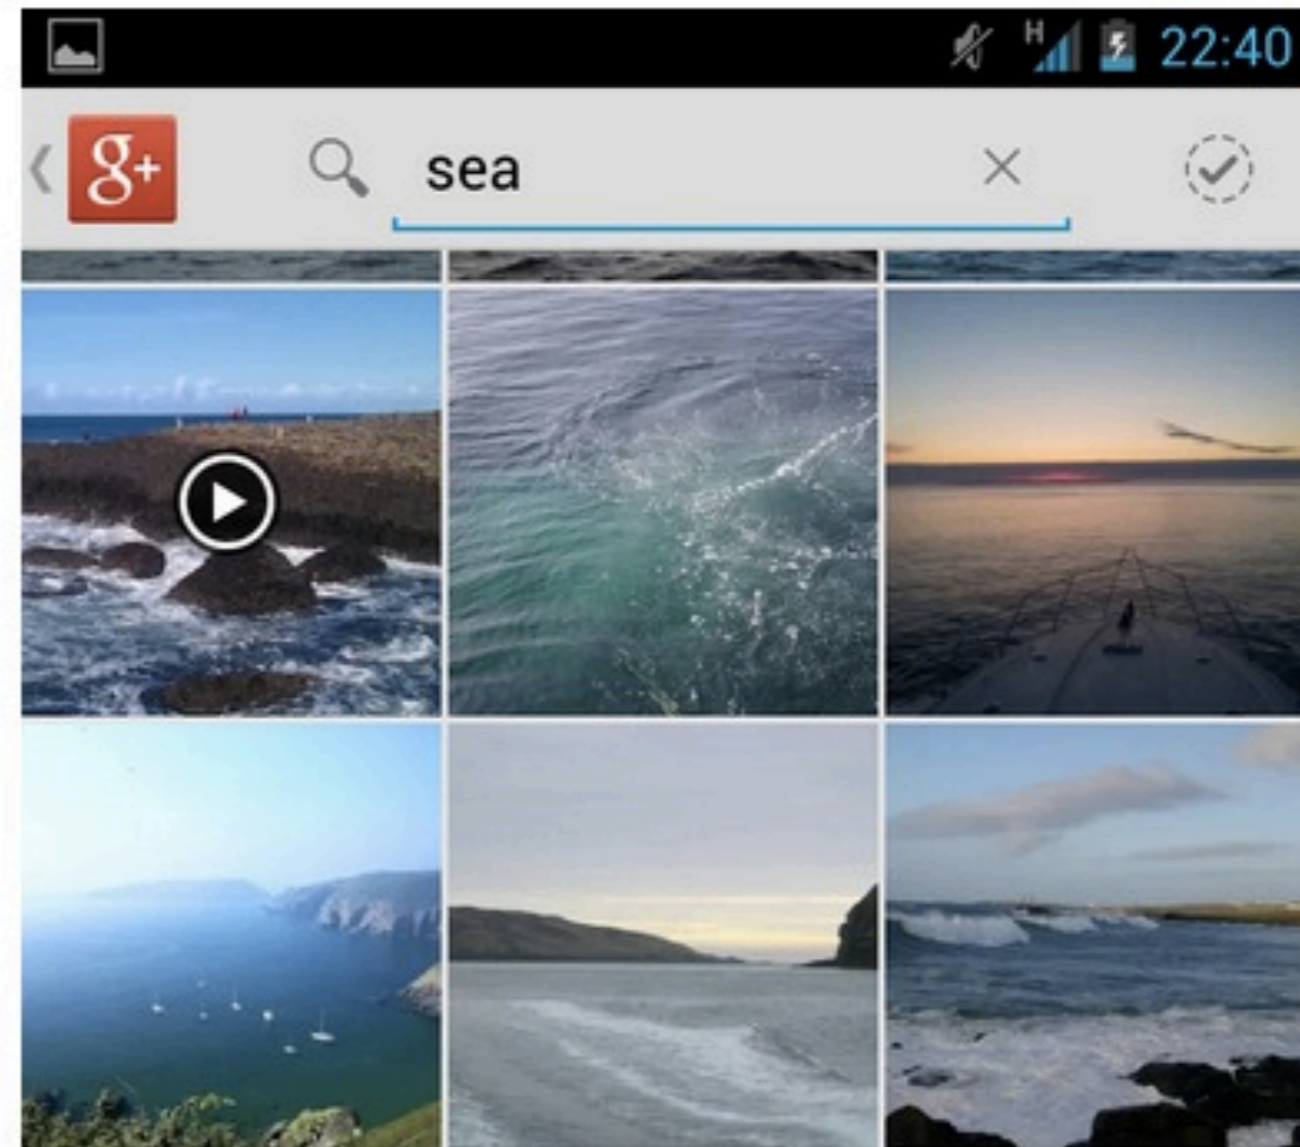

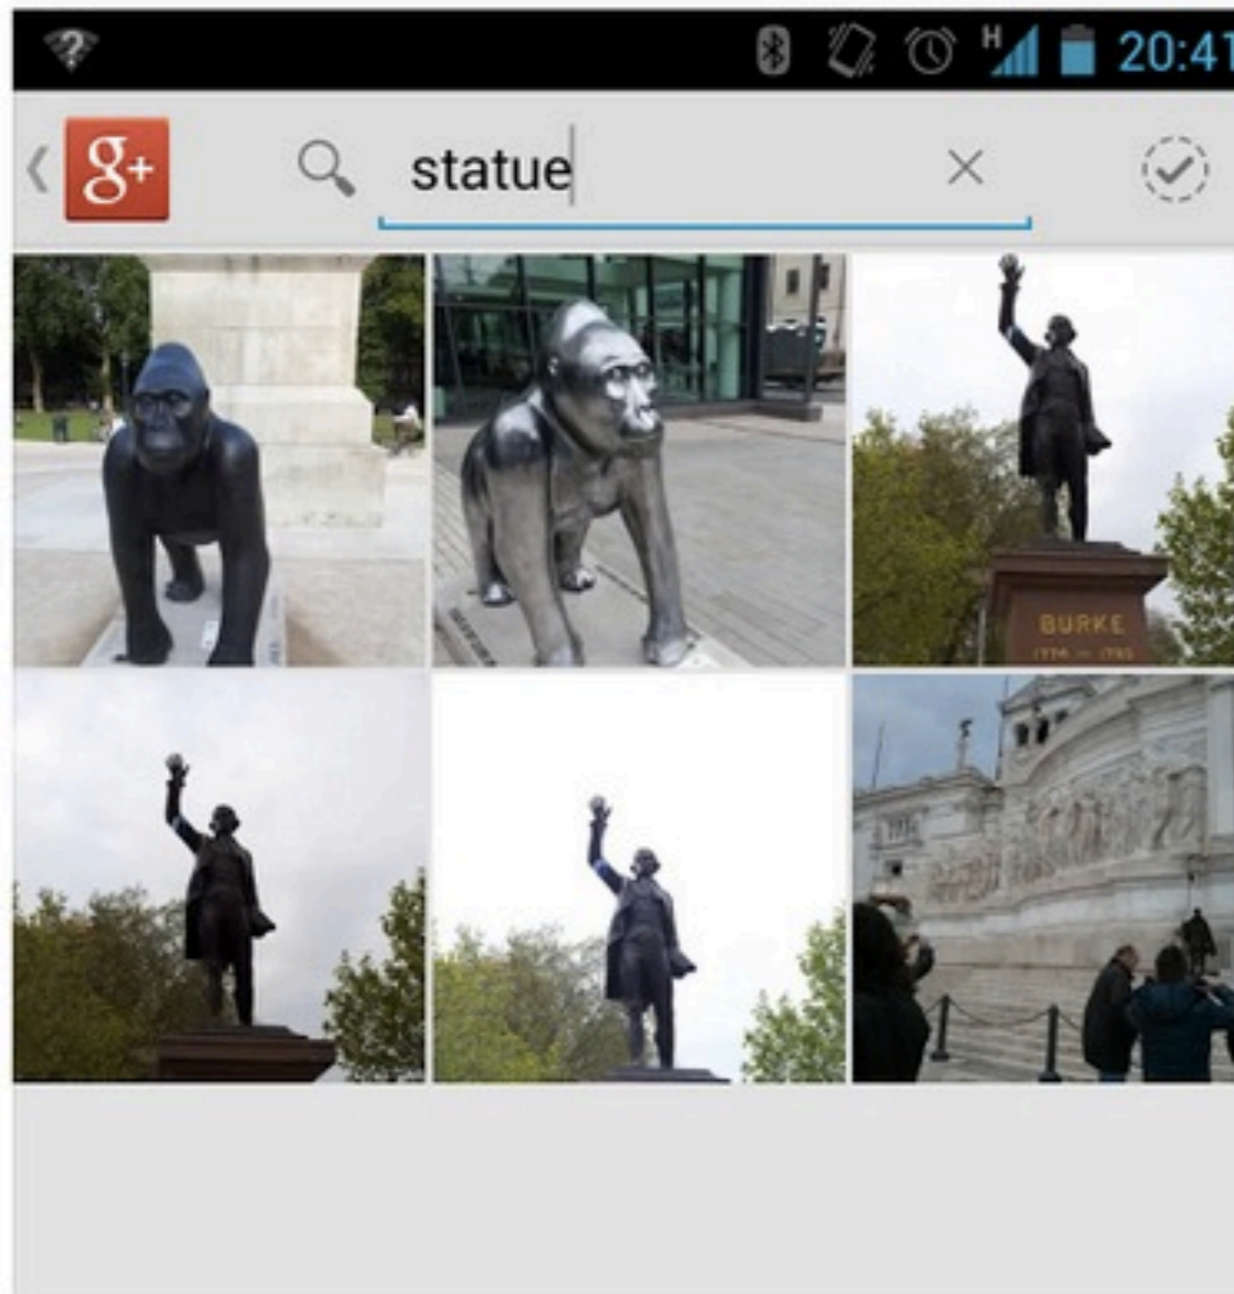

Basic architecture developed by Krizhevsky, Sutskever & Hinton  
(all now at Google)

Convolutional nets developed by Yann LeCun (of NYU)

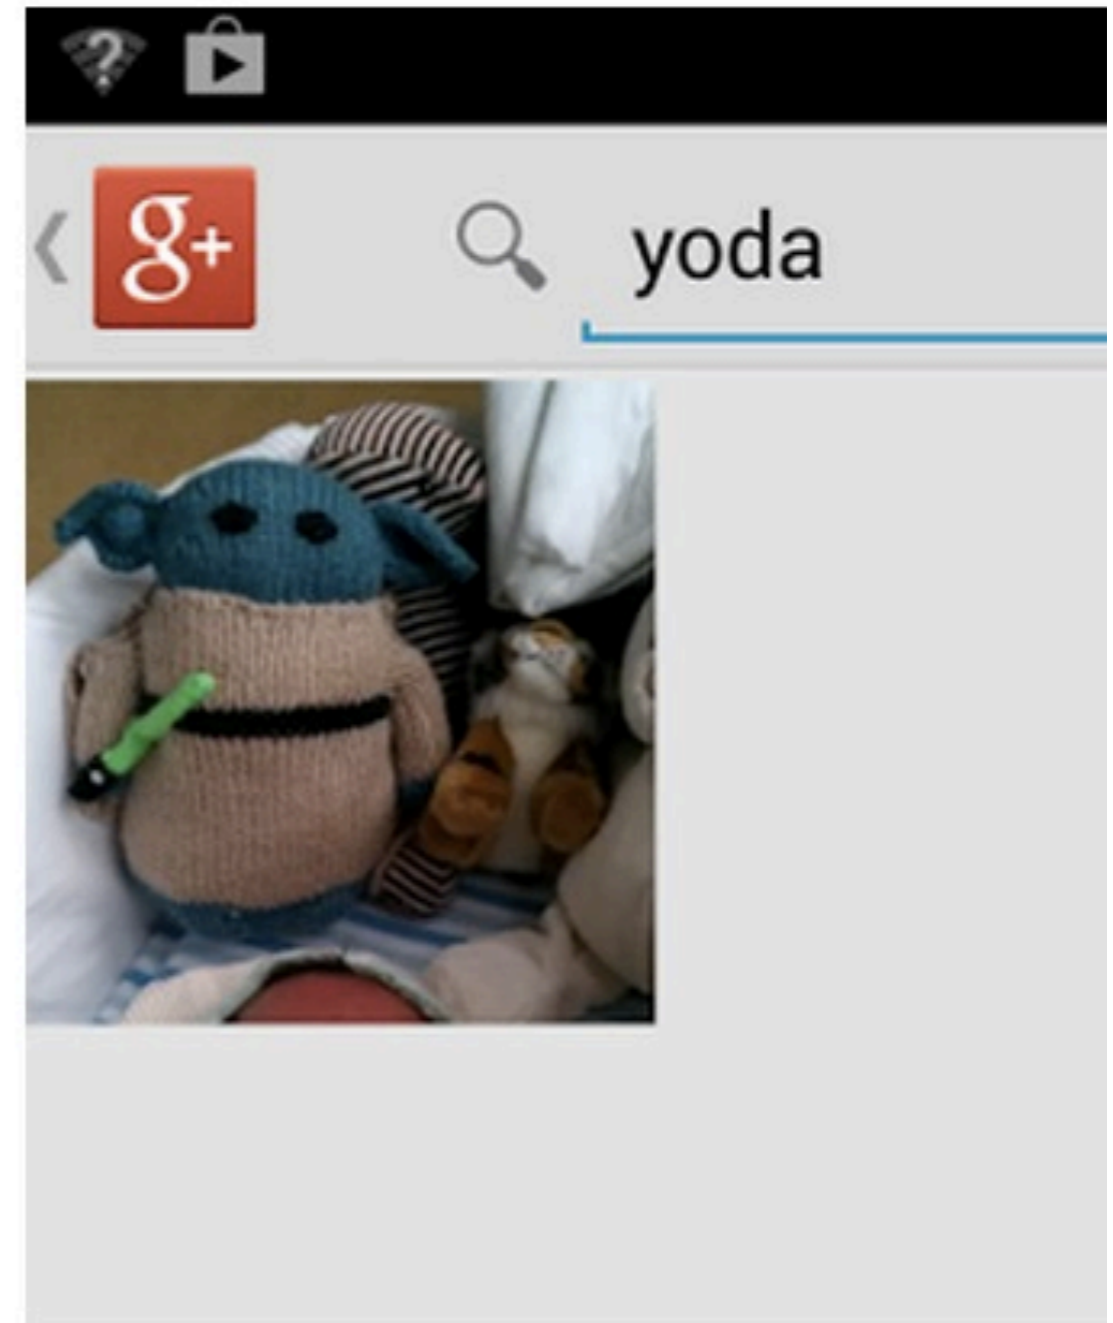

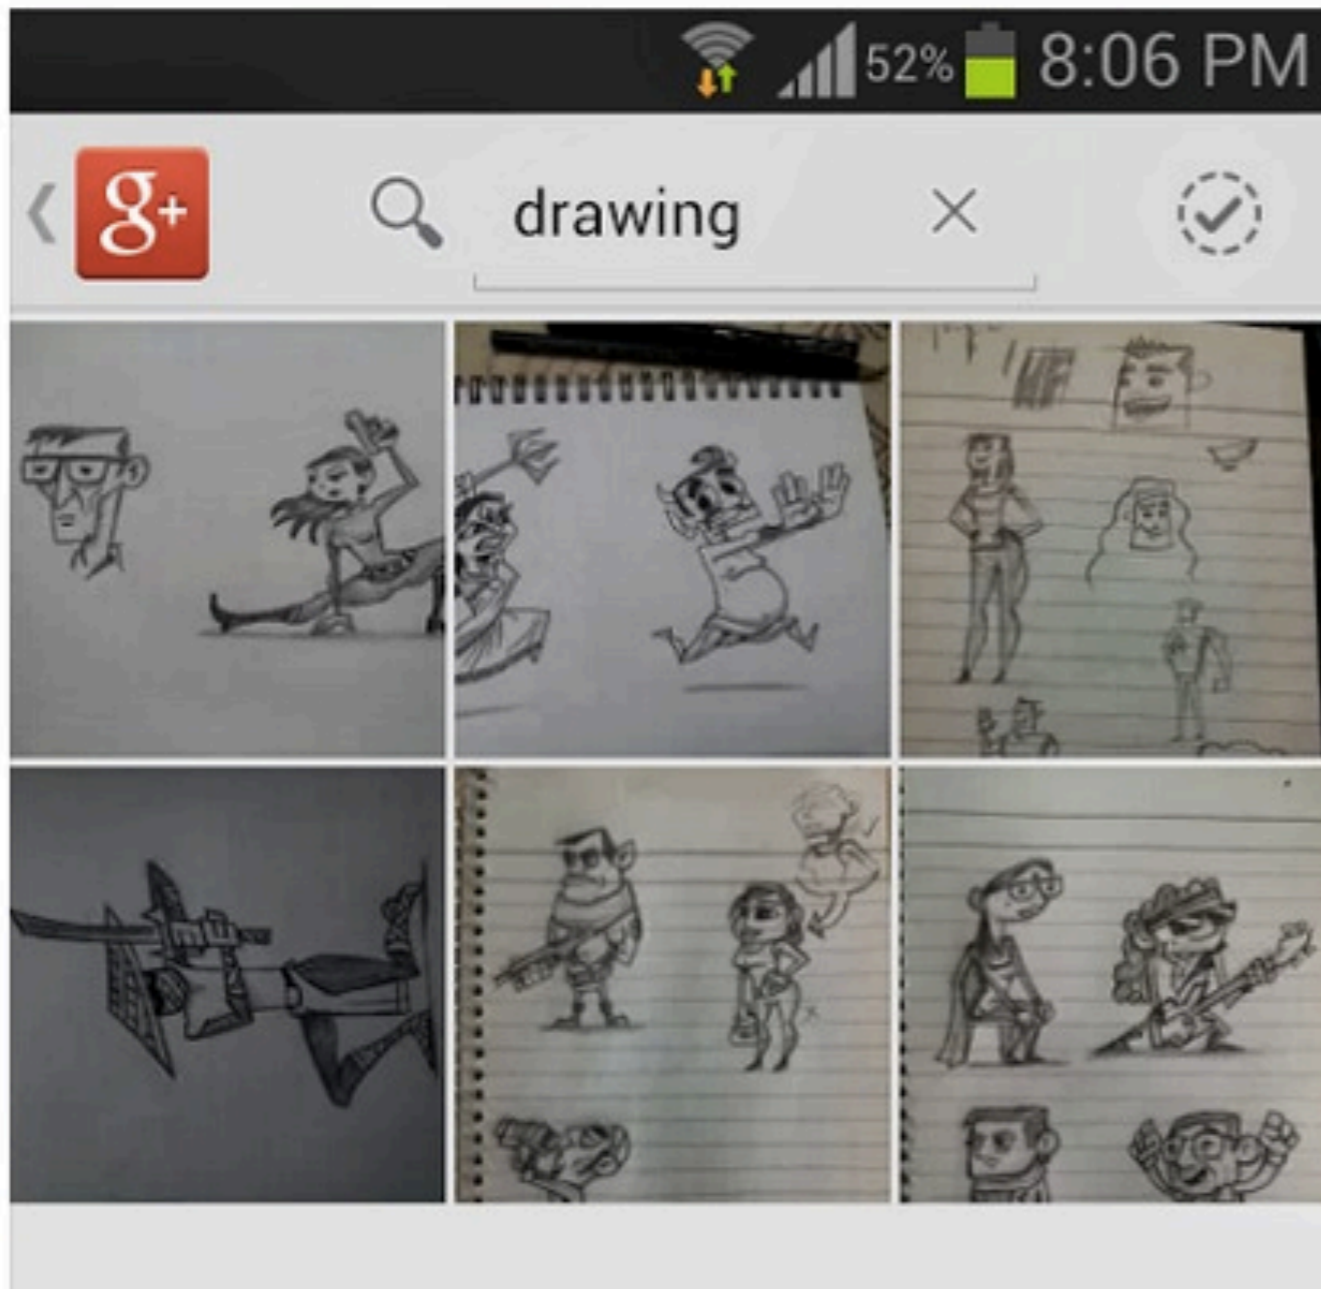

Wow.

The new Google plus photo search is a bit insane.

I didn't tag those... :)

Google Plus photo search is awesome. Searched with keyword 'Drawing' to find all my scribbles at once :D

# Solving Analogies

- Embedding vectors trained for the language modeling task have very interesting properties (especially the skip-gram model).

# Solving Analogies

- Embedding vectors trained for the language modeling task have very interesting properties (especially the skip-gram model).

$$E(\textit{hotter}) - E(\textit{hot}) + E(\textit{big}) \approx E(\textit{bigger})$$

$$E(\textit{Rome}) - E(\textit{Italy}) + E(\textit{Germany}) \approx E(\textit{Berlin})$$

# Solving Analogies

- Embedding vectors trained for the language modeling task have very interesting properties (especially the skip-gram model).

$$E(\textit{hotter}) - E(\textit{hot}) + E(\textit{big}) \approx E(\textit{bigger})$$

$$E(\textit{Rome}) - E(\textit{Italy}) + E(\textit{Germany}) \approx E(\textit{Berlin})$$

Skip-gram model w/ 640 dimensions trained on 6B words of news text achieves 57% accuracy for analogy-solving test set.

# Visualizing the Embedding Space

# Important Problems w.r.t. Representations

- Representing data in both raw form and in terms of high level representations derived from raw data will be important
- If we want to store and manipulate derived features in addition to raw data:
  - how do we design systems to perform fast high-level queries against large corpora?
  - how do we automatically and quickly incorporate new data into our model of the world?
  - how do we generalize from one particular task to many other tasks?
  - how do we minimize human effort for accomplishing all of this?

# Automatic Representations

- In the future, I believe:
  - Systems will become more self-managing and self-tuning
  - Automatically building high-level representations from raw data will be key to answering difficult queries about raw data
  - Being able to combine many different types of data together will be important

# Thanks!

- Questions? Thoughts?
